

Squad Hunza . Week 3 . Report

Comebck Pakistan, Cohort 1, Product Challenge
Week 3, submitted by Misbah on behalf of Squad Hunza

1. Overview

This report covers Week 3 of Squad Hunza's build for the Comebck Pakistan Product Challenge. The core decisions this week were the product name, the visual brand direction, and the final feature scope for the MVP. Backend access (Supabase) has been shared across the team, and work division across frontend, backend, and automation is being finalized directly with our mentor following this week's session.

2. Product Identity

Product name: Sortdesk

Sortdesk is an AI powered Gmail agent built for HR recruiters. It automatically sorts, prioritizes, and summarizes incoming candidate emails, and drafts context aware replies that a recruiter reviews and sends with one click. The name reflects the core job the product does: it sorts a recruiter's desk for them.

2.1 Visual Brand Direction

The product is designed around a professional dashboard feel. This means a clean, low distraction interface built for someone working through a high volume inbox during a busy hiring day, not a playful or consumer facing look. Typography and layout choices should favor clarity and speed of scanning over decoration.

2.2 Color Palette

The palette below was finalized this week and will be used consistently across the dashboard, chatbot interface, and any reporting or marketing material going forward.

Hex Code	Swatch	Role
#2C1320		Primary / Deepest tone
#5F4B66		Secondary / Panels
#A7ADC6		Accent / Highlights
#8797AF		Accent / Secondary UI elements
#56667A		Accent / Muted text and borders

3. Key Features, Finalized MVP Scope

The following features were confirmed in this week's team meeting and represent what we are actually committing to build for the MVP. This list is intentionally narrower than our original idea, in line with the challenge's guidance to go narrow and deep.

- AI email categorization across 10 defined candidate email categories.
- Priority detection with three levels: high, medium, low.
- AI draft reply generation, sent only after one click human approval from the recruiter.
- Candidate timeline showing what stage of the hiring process each applicant is currently at.
- Dashboard overview showing new applicants, follow ups needed, and scheduled interviews at a glance.
- Voice search, already integrated into the product through the React based chatbot.

4. Features Cut From Scope

These were considered and deliberately removed to keep the MVP focused and to conserve API token usage, which directly affects cost and speed at scale.

- Email summarization, removed to conserve API tokens.
- Standalone action required detection, removed because recruiters can identify required actions themselves once an email is categorized and prioritized correctly.
- A separate needs attention queue, removed in favor of the three level priority system, which achieves the same outcome with less complexity.
- Attachment and resume understanding, removed from current scope.

Cutting these features is a scope decision, not a quality compromise. Sorting, prioritization, and reply drafting are the features recruiters actually asked for in our research, and this is where our build time is going.

5. Technical Decisions This Week

- Supabase access has been shared with the full team so all three technical roles, frontend, backend, and automation, can work against the same database tables.
- API endpoints are planned to be created for all database tables, so frontend and automation work can proceed against a stable backend contract instead of building around gaps.
- A PDF extraction library is being evaluated for resume parsing so that we avoid burning API tokens on plain text extraction that a library can handle for free.
- We are weighing simple machine learning against full AI based automation for parts of the pipeline, since simple ML can cut API token usage significantly on tasks that do not need a language model.

- A bring your own key model is planned for future paid users, but this is post MVP and not part of the current build.

6. Work Division

Work division across the three technical roles, frontend UI, backend API integration, and automation, is currently pending. We met with our mentor this week specifically to get guidance on how to divide this work properly instead of assigning it ourselves without direction. The finalized division will be documented in next week's report once it is confirmed.

7. Next Steps

- Finalize task division with mentor input and assign owners to frontend, backend, and automation.
- Begin backend build work first, per the team's agreed sequencing, before frontend development starts.
- Push code incrementally to the shared GitHub repository starting this build phase.
- Confirm and document token usage findings for priority detection versus alternative approaches.
- Continue validating which features save the most time for actual HR users, to guide any further scope decisions.
